Fjordvik guardrails re-test report

The independent re-test of commit b7b9203, the fixes that followed, what the guardrails still don't catch, and when to test again. 2 November 2026. Synthetic data only: Fjordvik Manufacturing Oy is fictional, and this is a portfolio project. It follows the first report, `guardrails-test-report-2026-11-02.pdf`.

Why a second test

The first test found 62 ways past the guardrail hook, and Attena fixed them in commit b7b9203. A different chat then re-tested that commit read only, so the fixes were checked by someone other than the chat that wrote them. It also looked for new gaps and for everyday work the stricter hook might now block.

What the re-test found

Part	Result
A, static checks	5 of 5 passed, including the 118 hook cases.
B, the first test's gaps	58 of 62 fixed, and all 51 earlier passes still held.
B, new cases	106 of 156 new cases got past the hook. Two were high: git commands that roll guardrail files back with their fingerprints, and renaming `.claude`, which switches the hook off. Two were regressions.
C, everyday work	44 of 56 everyday calls allowed. The other 12 were false positives, such as a chained `git add`, `git commit` and `git push -u`.
D, fingerprints and layout	12 of 12 fingerprint changes caught. Some layout names were too strict, such as a future `pump_temp` table.
E, live calls	14 of 14 as expected.
F, the first report	Every figure matched its evidence. A few wording points were raised.

Attena reproduced 11 of the 12 findings it checked before changing anything, including both highs and both regressions.

How the findings were sorted

Reece asked for the realistic 95% of cases to be covered, not every edge case, and for a point where re-testing stops. Each finding was sorted by one question: could a chat plausibly run this in normal work or by mistake? Those were fixed. Forms that only a deliberate attempt to get round the hook would use went on a known-limits list in `GUARDRAILS.md` instead, such as a quoted `"git"` or a path held in a variable.

Blocking writes at the operating-system level was researched first. Claude Code's sandbox doesn't run on native Windows, only inside the Windows Subsystem for Linux, so it isn't available on this laptop. Claude Code's own permission rules are, and they now form a second layer.

What was fixed

- **Rollbacks and moves (G9).** The hook asks before a git reset, revert, restore or checkout that would change a guardrail file, and before moving or renaming `.claude`, `guardrails` or `data`.
- **Wrapped commands.** Commands inside `bash -c`, `cmd /c`, `powershell -Command`, `eval` and `iex` are checked like any other. A command the hook can't read, such as an encoded one, asks.
- **More shell forms (D3).** More writing commands, Python heredocs and inline code, subshells, line

continuations and the `&>` redirects are read. git commands that remove generated files are blocked.

- **Files sent out (D8).** Artifact and SendUserFile are now checked, and PowerShell wildcards that would match a `.env` file are blocked.
- **git hooks (G2).** Writes to `.git/hooks/` are blocked, and each part's `tests/test_guardrails.py` is now protected and fingerprinted.
- **False positives.** git rules read each command in a chain on its own and ignore commit messages. Copies are judged only by where they write, and text in quotes is no longer read as a redirect.
- **Permission rules.** `.claude/settings.json` now holds deny rules for `.env` files, the generated folders and `.git/hooks/`, and ask rules for the guardrail files. Claude Code applies them in every mode, whatever form a path takes. A hook that times out now blocks.
- **Names.** L5 no longer flags words a project needs (temp, debug, copy, old) and now reads folder names. Proposal names need a chat name, and evidence dates must be valid calendar dates.

Results after the fixes

Check	Result
The re-test's earlier cases, rebuilt and rerun	106 of 112 as expected. The other 6 behave the same on the previous hook: 4 known leftovers and 2 cases the rebuild script can't reproduce.
The re-test's new cases	121 of 153 as expected. All 32 others are on the known-limits list.
Everyday work	54 of 56 allowed. `rm -rf */__pycache__` asks, and a search for `.env` in an ignore file is blocked by design.
Hook test in `shared_tests.py`	154 cases (83 block, 40 allow, 31 ask), all passing.
Permission rules, live	A redirect form the hook misses was refused by Claude Code's own project rule.
`check.py`	No findings, with eleven fingerprinted files.
Each part's full tests	data 96 passed; mcp 83 passed; powerbi 579 passed, 154 skipped; power-automate 30 passed; service-ai 6 passed. Every count matches the baseline.

While saving this evidence, the hook blocked one of Attena's own commands, because quoted text contained a redirect. That false positive was fixed and added to the hook test.

What the hook still doesn't catch

`GUARDRAILS.md` lists the forms in full, in "What the hook doesn't catch". In short: unusual git spellings, paths built at run time, quoting inside a name, unusual Windows paths, a few rare shell forms, and commands over 20,000 characters, which ask instead. Backstops cover these cases. The data tests catch any change to generated tables, and the fingerprints catch any change to the guardrail files. The permission rules cover file tools and redirects, and the pre-commit check runs before each commit.

When to test again

One final re-test follows, scoped to the realistic cases, at least 50 everyday calls and the earlier passes. It passes with no high finding, no realistic medium gap and no everyday false positive. Forms it finds that only a deliberate attempt would use go on the list without a code change. After that, the guardrails are tested again only when a rule or the hook changes, or a chat hits a real incident.

What stays open

- The final re-test, by a fresh chat.
- D7, which allows illustrative emission factors, differs from RULES.md. That is for Reece and A-ron.

- Three proposals wait for their owners: the root README and CLAUDE.md lines, `intake_rules.py` in power-automate, and where service-ai's learning notes go.

Prepared by Attena, the Fjordvik guardrails chat, from the retester's note of 2 November 2026 and Attena's own checks, saved in `guardrails/evidence/`. The fixes are in the commit after b7b9203 on `guardrails/first-update`.
